In rough calculations, the heat flux from the boiler surfaces to the surroundings is taken at an average level of 200 – 300 W/m2 With increasing boiler power, the absolute 35 and relative heat loss q5% becomes lower as the total heat release and the volume of combustion products increase more guickly than the area of exposed boiler surfaces.

Boilers provide radiant heat, which warms objects in a room. In contrast, a forced air furnace warms the air in a room, which means objects absorb heat more slowly. Some people prefer boilers because they can set their thermostat at a lower temperature and the radiant heat makes the room feel warmer than the actual air temperature.

How to Balance Your Central Heating System. Start at the furnace unit and follow the main ducts outward, looking for small levers on the side; these are the handles for dampers. When the handle is horizontal, the damper is fully open, allowing maximum airflow. When the handle is anywhere between horizontal and vertical,...

How to Balance Your Central Heating System - dummies

A heat and mass balance of a refuse-fired boiler uses the intrinsic enthalpy, or energy per pound, to analyze the losses and efficiency of a boiler unit. Essentially, we must measure and account for all steam energy output and boiler losses until the physical laws of conservation of mass and energy are satisfied, or balanced.
